ABSTRACT Researchers have collected Twitter data to study a wide range of topics. This growing body of literature, however, has not yet been reviewed systematically to synthesize Twitter-related papers. The existing literature review papers have been limited by constraints of traditional methods to manually select and analyze samples of topically related papers. The goals of this retrospective study are to identify dominant topics of Twitter-based research, summarize the temporal trend of topics, and interpret the evolution of topics within the last ten years. This study systematically mines a large number of Twitter-based studies to characterize the relevant literature by an efficient and effective approach. This study collected relevant papers from three databases and applied text mining and trend analysis to detect semantic patterns and explore the yearly development of research themes across a decade. We found 38 topics in more than 18,000 manuscripts published between 2006 and 2019. By quantifying temporal trends, this study found that while 23.7% of topics did not show a significant trend ($P > 0.05$), 21% of topics had increasing trends and 55.3% of topics had decreasing trends that these hot and cold topics represent three categories: application, methodology, and technology. The contributions of this paper can be utilized in the growing field of Twitter-based research and are beneficial to researchers, educators, and publishers.

INDEX TERMS Literature Review , Social Media, Survey, Text Mining; Topic Modeling, Twitter

I. INTRODUCTION

Twitter is a social media platform for computer-mediated online communication, which shapes an emerging social structure. This communication platform has 1.3 billion accounts and 336 million active users posting 500 million tweets per day [1]. Twitter users can post comments known as “tweets,” each restricted to 140 characters prior to October 2018 and currently, 280 characters. Unless tweets are made private, they are publicly available and Twitter users can show their reaction to and engagement with a tweet by sharing it on their profile (retweet), clicking the like button, tagging someone’s user name, or responding to the author of the tweet [2].

Twitter has also provided Application Programming Interfaces (APIs) to facilitate data collection. To access the API, a user can apply for a developer account¹. Following the application approval, the user has access to four keys:

consumer key, consumer secret, access token, and access secret [20]. These keys authenticate the user to access Twitter data such as tweets and profile information. Twitter’s own API is the most potent available tool for collecting data generated through the interaction of Twitter users. Representing different demographic categories, Twitter data is a diverse and salient data source for researchers [21]–[23] and policymakers [24].

This global data source has earned the focus of several studies to address a wide range of research questions in different applications such as health and politics [25], [26]. While most studies used Twitter APIs for data collection such as [27], other studies manually collected data like [28], acquired Twitter data from commercial companies such as [29], or utilized previously collected data from other studies like [30].

The diverse interests of interdisciplinary fields, like Twitter-based research, have constantly been evolving.

Twitter-related studies have experienced an explosion of research development during the last decade. To reflect this development, some papers have reviewed relevant scientific publications systematically through traditional literature reviews. Table 1 shows the related studies found in the Google Scholar and Web of Science databases using two queries: “Twitter AND Survey” and “Twitter AND Review.”

We have extracted some relevant features of these studies such as data collection method, number of analyzed papers, topic(s), and whether each included trend analysis. For the studies which did not mention the exact number of analyzed Twitter-based papers, we assumed the maximum number of reviewed papers was equal to the total number of references (#Ref). In the case of articles without research time frame information, we assumed the maximum range of time frame was the difference between the publication year and the launching year of Twitter that is 2006. For example, if a paper was published in 2012, the maximum number of years (#Years) is 6 (2012-2006).

While the relevant studies in Table 1 provide valuable insights, these studies have some limitations. First, a traditional literature review process starts with a large number of manuscripts. However, this manual process is not feasible. Therefore, researchers limit the number of papers to review – meaning that only a sample of relevant papers was selected, not all relevant papers [31]. Second, the first limitation indicates that the traditional approach could be prone to various biases such as focusing on journal articles and highly cited authors or studies [32]. Third, the traditional literature review process is not efficient, resulting in a time-consuming and labor-intensive process with a small sample of papers. For example, the maximum number of Twitter-related papers analyzed in a study was less than 160. Fourth, the existing literature does not provide a temporal trend perspective. Fifth, the current studies are too specific to a few topics, often only one. Sixth, they did not show a macro-level perspective that synthesized major disciplines and applications from the literature. Seventh, it is a difficult task to replicate and compare the results.

This study combats these limitations using a systematic ap-

proach to collect and analyze all relevant abstracts containing a condensed representation of the breadth of interdisciplinary Twitter-related studies. This endeavor can provide a macro-level intellectual viewpoint to track dynamic semantic patterns of what has been accomplished and what could be in future Twitter-based research.

Given the large number of Twitter-related studies, a systematic review can provide a valuable perspective to better define the literature landscape. The goals of this retrospective study are to identify dominant topics of Twitter-based research, summarize the temporal trend of topics, and interpret the evolution of topics within the last ten years. To achieve these goals, utilizing computational methods offers a promising, more time efficient route [33]. Therefore, we applied text mining and trend analysis to reveal the main research themes and trends in the abstracts of more than 18,000 papers published between 2006 and 2019. Text mining is an effective and efficient approach that has been applied in a wide range of research interests. With the purpose of organizing and understanding documents, text mining disclosed hidden semantic patterns in a corpus. Then trend analysis, or the process of measuring the variation of topic distributions over several years, made it possible to track the temporal changes of research activities across the years represented in the corpus.

The contributions of this paper are four-fold. First, this is the first research that investigates thousands of papers to disclose the main themes of Twitter-related studies. Secondly, the proposed framework offers a fully functional approach to review a large number of research papers of any discipline and track their trends across several years. So, our approach can be utilized to understand the landscape of additional fields of research. Thirdly, the publicly available data of this research can be used to pursue further studies or replicate results of this study. Fourth, the trend analysis aids both supplies an overview of past research as well as insights for future research.

II. METHODS

This section introduces our research framework in four phases: data collection, frequency analysis, topic modeling,

FIGURE1: Research Framework.

topic analysis, and trend exploration (Figure 1).

A. DATA COLLECTION

To better understand the current status of Twitter research, studying the content of journal and conference publications can help us to detect methodological and practical concepts [34], [35]. The abstract of an article contains concise information which discloses the larger picture of the article. We retrieved relevant abstracts containing “twitter” in their title or abstract from three major databases: Web of Science (WOS)², EBSCO³, and IEEE⁴ in March 2019. We focused on the journal and conference abstracts published between 2006 and 2019. The collected data is available at <https://github.com/amir-karami/Twitter-Research-Papers> (Figure 1).

B. FREQUENCY ANALYSIS

Published in various domains, the abstracts are unstructured textual data and needed to be deciphered. Text mining techniques can provide exploratory analysis to detect semantic patterns [34]. To have an overall perspective, we analyzed the frequency of top-10 and top-50 words using the bar chart and word cloud, respectively. A word cloud represents the frequency of words in a corpus using word size – where larger size denotes higher frequency [37] (Figure 1).

C. TOPIC MODELING

As one of the most popular text mining methods, topic modeling is an efficient and systematic approach to analyze thousands of documents in a few minutes [38]. Among topic

models, Latent Dirichlet Allocation (LDA) [39] is a valid and widely used model based on statistical distributions [40]–[44]. LDA assumes that there is an exchange between words and documents in a corpus representing by bag-of-words. LDA identifies semantically related words, which occur together in multiple documents of a corpus. These word lists or “topics” are then interpreted by human intuition as meaningful “themes” [45]. For example, LDA assigns “gene,” “dna,” and “genetic” to a theme interpreting as “genetic” (Figure 2).

LDA has been applied on both long-length (e.g., abstracts) and short-length (e.g., tweets) corpora for different applications such as health [27], [46]–[50], e-petitions [51], politics [30], [52], [53], analysis of sexual harassment experiences [54], [55], opinion mining [56], [57], automatic summarization [58], investigation of social media strategy [59], [60], SMS spam detection [61], transportation literature [62], adolescent substance use and depression [63], and mobile work [64], and literature review surveys relevant to depressive disorder [65], wearable technology [66], biomedical [37], [67], and medical case reports [38].

We considered abstracts as our documents, hereafter using abstract and document as interchangeable terms. LDA assigns a degree of probability for each set of words with respect to each of the topics and a degree of probability for each of the topics with respect to each of the documents. In summary, LDA identifies the relationship between the topics and documents, $P(T|D)$, and words and topics, $P(W|T)$ (Figure 1). For n documents (abstracts), m words, and t topics, the outputs of LDA were: the probability of each of the words given a topic or $P(W_i|T_k)$ and the probability of each of the topics given a document or $P(T_k|D_j)$ (Figure 3). The top words per each topic, based on the descending order

FIGURE2: An Example of LDA [36].

$$LDA \rightarrow_{Words} \begin{bmatrix} P(W_1|T_1) & \dots & P(W_1|T_t) \\ \vdots & \ddots & \vdots \\ P(W_m|T_1) & \dots & P(W_m|T_t) \end{bmatrix}_{Topics} \&_{Topics} \begin{bmatrix} P(T_1|D_1) & \dots & P(T_1|D_n) \\ \vdots & \ddots & \vdots \\ P(T_t|D_1) & \dots & P(T_t|D_n) \end{bmatrix}_{Documents}$$

FIGURE3: Matrix Interpretation of LDA

of $P(W_i|T_k)$, were used to represent the topics. We also used $P(T_k|D_j)$ to find the weight of topics per year. For example, if the first 100 abstracts (D_1, D_2, \dots, D_{100}) were published in 2009, the weight of T_1 in 2009 would be $\sum_{j=1}^{100} P(T_1|D_j)$.

D. TOPIC ANALYSIS

The inferred words of topics do not have inherent meaning without additional qualitative analysis. Two of the authors coded the topics independently by investigating the top-10 words based on descending order of $P(W|T)$ and top-5 abstracts based on descending order of $P(T|D)$ to decode the content of topics (Figure 1). For the disagreements, the two coders employed another round of annotation. Finally, a third annotator resolved any remaining disagreements. For example, the coders assigned "Politics" label to T_2 based on exploring the top-10 words ("political, twitter, election, campaign, candidates, politicians, parties, party, elections, communication") in Table 2 and investigating top-5 documents ([68]–[72]) inferred by LDA.

E. TREND EXPLORATION

Statistical trend analysis of topics can aid in detecting hidden temporal patterns to move beyond surface-level observations about research trends. To explore the trends, we used a linear trend model to track the weight of topics within each year using $P(T|D)$ [65]. We used the R *lm* function to measure $P - Value$ and slope for each of topics. The $P - Value$ determines whether a trend is significant or meaningful ($P < 0.05$) and the slope shows whether a trend is increasing (hot) or decreasing (cold) (Figure 1).

III. RESULTS

After removing duplicate records, we found 18,849 unique abstracts written in English, published between 2006 and 2019. Figure 4 shows the total number of published papers per year over more than one decade along with the trend line, which illustrates a significant change ($P < 0.05$) with a positive slope indicating an increasing trend. Due to incompleteness, the 2019 papers published were excluded from the figure.

FIGURE4: Frequency of Twitter-related studies from 2006 to 2018.

There were 1,706,918 tokens, of which 30,506 words were unique. Word frequency analysis illustrated that more than 90% of the unique words had less than 100-frequency. The word frequency ranged between 2 and 38,219 occurrences with a median 5 and average 55.95. Figure 5 shows the

alignment between the frequency of words and Zipf's law stating the inverse relationship between the frequency of words and their frequency rank [73]. This figure also shows the position of the top-50 words among more than 30,000 words in the word cloud using the vertical line.

FIGURE5: Frequency of words. The vertical line shows the cut-off point for the top-50 words in the word cloud.

Figures 6 and 7 show the top-10 high-frequency words and the top-50 high-frequency words using the bar chart and word cloud, respectively. We saw three categories of words. The first one was expected-social media words such as “*users*” and “*tweets*” which were among the high-frequency words. The second category represented common research paper-related words like “*data*,” “*information*,” “*use*,” “*study*,” and “*analysis*.” The third category illustrated research topics such as “*health*,” “*political*,” “*news*,” and “*behavior*.”

Beyond preliminary frequency assessments, we used LDA to disclose the hidden semantic structure of papers. LDA has an important pre-processing step, which is defining the optimal number of topics. We used the latent concept modeling [74] to estimate the optimum point. This model maximizes the overall dissimilarity between the word distributions of topics. Using the *ldatuning* R package⁵, we found the optimum number of topics at 40 by applying the latent concept modeling on the number of topics from 2 to 100. After removing stop words (e.g., “the” and “a”), we applied the Mallet implementation of LDA [75] with its default settings on the abstracts to detect the 40 topics.

To evaluate the robustness of LDA, this study investigated the log-likelihood for five sets of 1000 iterations (Figure 8). The comparison of the mean and standard deviation of iterations showed that there was not a significant difference ($P > 0.05$) in log-likelihood convergence over the iterations.

Table 2 and Figure 9 show the detected 40 topics and their weight, respectively. For example, T_2 was named “*Politics*” based on interpretation of “*political, twitter, election, campaign, candidates, politicians, parties, party, elections, communication*.”

We removed T_1 and T_{12} because T_1 was an unrelated topic representing animal calls and T_{12} contained common terms

⁵<https://cran.r-project.org/web/packages/ldatuning/vignettes/topics.html>

found in writing abstracts that cannot be mapped to a specific research theme. The weight of topics ranges from 0.044 for sentiment analysis to 0.014 for image/video analysis with median 0.024 and average 0.026. After the coding process and removing the two unrelated topics, we investigated the yearly trend of 38 topics based on aggregating $P(T|D)$ at the year level for ten years from 2009 to 2018 (Table 3). Due to the low number of publications, we did not consider 2006, 2007, and 2008 trends. Out of the 38 topics, nine topics did not have significant trends ($P \geq 0.05$), but 29 topics had significant trends ($P < 0.05$) including 21 hot and 8 cold topics. Among the 29 topics with a meaningful trend, 17 topics had extremely significant ($P < 0.001$), 4 topics had very significant ($P < 0.01$), and 8 topics had significant ($P < 0.05$) changes (Figure 10).

To provide examples for each of the 38 meaningful topics and better illustrate their relevance, the coders analyzed the five most related papers for each of the topics based on descending order of $P(T|D)$. The following summaries provide more details based on studying 190 articles (5 articles per topic \times 38 topic) offered by LDA. We also provide useful additional resources for methodology-related topics.

Politics. Several studies have utilized Twitter data for election purposes such as the impact of Twitter adoption on the voting behavior of congressmen [68], analyzing populist social media strategies of political actors [69], examining the Twitter engagement between the candidates and followers in the 2010 US midterm elections [70], investigating the variance in partisan rhetoric of the US senators in their tweets [71], and examining the tweets posted by the candidates during the Australian federal elections in 2013 and 2016 [72]. Having an extremely significant change ($P < 0.05$), politics-related twitter studies have a positive slope indicating increasing research activity.

Disaster Analysis. This category of study has used Twitter data for disaster analysis such as investigating the activity of rumor-spreading users and the debunking response behaviors during Hurricane Sandy in 2012 and the Boston Marathon bombings in 2013 [76], understanding how retweets spread information during the Fukushima nuclear radiation disaster [77], investigating the difference between the information shared on public safety organizations' websites and their twitter accounts during the 2015 winter storms in Lexington, KY [78], analyzing the tweets of government organizations during Hurricane Harvey to disclose their disaster response strategies [79], and examining the use of weather warning related hashtags to disclose their effectiveness for information retrieval and processing [80]. The trend analysis does not show a significant change ($P > 0.05$) for the disaster analysis category.

Sentiment Analysis. This topic represents a research methodology that aids researchers in assessing whether the sentiment polarity of tweets is positive, negative, or neutral. The studies reviewed here proposed new methods for sentiment analysis purposes such as using N-gram analysis based on diabetes ontologies for aspect-level sentiment

analysis [81], exchanging sentiment labels between words and tweets using feature vectors to reduce the cost of data annotation in supervised methods [82], utilizing a pattern-based approach to classify tweets into seven classes including happiness, sadness, anger, love, hate, sarcasm and neutral [83], proposing a supervised sentiment analysis method using emotion-annotated tweets, unlabeled tweets, and hand-annotated lexicons [84], and utilizing semantic relationships between words and n-grams analysis for measuring public sentiment [85]. Like the politics-related twitter studies, sentiment analysis has a positive slope indicating increasing research activities over time. For extensive details and discussions on sentiment analysis, refer to [86], [87].

Topic Modeling. This method discloses the hidden semantic structure of tweets. The studies in this theme have proposed customized topic models for Twitter data or utilized already developed topic models such as incorporating Twitter-LDA, WordNet, and hashtags to enhance the quality of topic-discovery [88], developing a topic model based on high utility pattern mining to detect emerging topics [89], utilizing an already developed method, called hierarchical Dirichlet processes (HDP), to detect all posts related a given event [90], proposing a model based on Latent Dirichlet Allocation (LDA) to extract key phrases for social media events [91], and integrating the recurrent Chinese restaurant process and word co-occurrence analysis to propose a nonparametric topic model for short text documents such as tweets [92]. It is worth mentioning that the studies that utilized pre-existing topic models used a qualitative approach for coding topics. In addition, the current topic models are based on five main approaches: linear algebra [93], probability [94], statistical distributions [39], neural networks [95], and fuzzy clustering [45], [96]–[98]. The topic modeling theme shows an extremely significant change with a positive slope. For more details and discussions on topic modeling, refer to [36], [95], [99]–[101].

Spatial Analysis. This technique examines Twitter geo-located data such as the assessment of spatial distribution of people's exposure to burglaries and robberies [102], exploring different types of human activities such as shopping in Boston and Chicago [103], creating population maps using geo-located tweets in Indonesia [104], mapping mobility patterns in one of Chile's medium-sized cities [105], and utilizing Twitter data for spatial analysis of crashes in Los Angeles [106]. The trend of spatial analysis illustrates an extremely significant change with an increasing slope. For more details on spatial analysis, refer to [107]–[110].

Digital Communication. This theme represents the papers which studied digital communication issues of Twitter such as investigating the impact of student interactions with social media on their daily lives [111], utilizing Twitter to promote library services [112], assessing fitness, diabetes, and meditation mobile applications based on communications in tweets [113], understanding how Twitter has changed the communication between surgeons and colleagues and patients [114], and investigating the Twitter application for medical com-

munication [115]. Having an extremely significant change, the digital communication theme shows a negative slope indicating decreasing research activities.

Medical Education. This theme shows the research on using Twitter for medical education purposes such as online discussion on program evaluation [116] and research papers [117], professional development [118], and utilizing Twitter in emergency medicine residency programs [119] and medical conferences [120]. Having a significant change, the medical education theme have a decreasing trend.

Ethics, Law, and Privacy. This theme represents the studies discussing ethical and privacy issues such as proposing ethical frameworks for social media platforms to better protect free speech and prevent harms [121], investigating the challenges of current laws for social media legal cases [122], exploring Twitter regulatory mechanisms to protect the users against criminal offenses [123], evaluating the freedom of expression on Twitter based on the interpretation of First Amendment [124], and understanding the legal position of Twitter's services in the US Federal criminal courts [125]. Having an extremely significant change, the theme of ethics, law, and privacy illustrates decreasing research activities.

Information Behavior. This theme includes papers that studied information behavior on Twitter such as examining the impact of content and context factors on retweeting [126], disclosing the motivations behind the continuous use of Twitter services [127], analyzing the factors impacting Twitter's perpetuation [128], investigating the brand-following behavior of Twitter users based on the theory of planned behavior [129], and understanding whether tweets can increase the news knowledge of users [130]. Having a significant change, the theme of information behavior analysis has a decreasing trend.

Social Movement. This topic analyzed the tweets of social movements such as the 2011 revolution in Egypt [131], 2011 revolution in Tunisia [132], 2011 occupy Wall Street protest [133], 2009 Iranian presidential election protests [134], and 2014 protests for the kidnapped and massacred students in Mexico in 2014 [135]. The theme of social movement does not show a significant change over time.

Social Media Platforms. This topic is illustrated by papers which explored and compared Twitter and other social media platforms such as Reddit, Foursquare, Tumblr, Instagram, Facebook, Wikipedia, and YouTube to address different research purposes such as exploring various definitions of social media [136], analyzing uses of social media platforms [137], investigating social media platforms for communication in academic libraries [138], understanding how radiologists use different social media platforms [139], and exploring the impact of social media on the competitiveness, structure, and processes of an organization [140]. The theme of social media platforms has a significant change with an increasing trend.

Content Analysis. This method discloses concepts, detects their relationships, and draws semantic inferences by interpreting and coding tweets. Examples of content analysis

studies include characterizing the content of tweets relating to indoor tanning [141], investigating the tweets containing bullying-related words [142], exploring tweets related to Planned Parenthood [143], analyzing the tweets related to kidney stones [144], and comparing the marijuana-related tweets posted before and after the 2012 US election [145]. While the topic modeling related studies analyzed the content of all collected tweets, the content analysis related papers investigated a small sample of tweets. For example, the researchers analyzing the bullying-related tweets selected a sample of 10,000 tweets from millions of potentially related tweets for content analysis. Like topic modeling, content analysis shows an extremely meaningful trend with a positive slope. For more details about content analysis, refer to [146]–[151].

Disease Surveillance. This topic represents the papers utilizing Twitter data for monitoring diseases such as the 2010 Haitian Cholera outbreak [152], 2015 Middle East respiratory syndrome outbreak [153], Chikungunya virus [154], Zika virus [155], and infectious eye diseases [156]. The theme of disease surveillance shows an extremely significant change with a positive slope indicating increasing research activities.

Social Media Technology. This theme covers the papers studying different aspects of social media technology such as information sources used by students [157], financial professionals [158], and library services [159] and exchanging health information [160], [161]. Having an extremely significant change, the theme of social media technology faces decreasing research activities.

Sport/Entertainment. This topic illustrates the manuscripts studying applications of social media for sport and entertainment such as campaigning against racism at the 2016 Oscars [162], TV [163], social media [164], and women's soccer [165], and the #metoo movement against sexual harassment and sexual assault [166]. The trend analysis shows that sport/entertainment related studies have a significant change with a positive slope indicating increasing research activities.

Big Data Mining. Having a foundation in statistics, artificial intelligence, and machine learning, this method detects patterns and correlations within big Twitter data for different applications such as sentiment analysis [167], opinion mining [168], analyzing structured and unstructured data [169], exploring the trend change of languages [170], and spatial analysis [171]. The trend analysis shows that big data mining is one of the attractive research topics with an extremely significant increase and change over time. For more details about big data mining, refer to [172]–[176].

Big Data Architecture. This topic represents the studies focusing on the architecture of big data such as proposing new platforms for analyzing real-time social media data [177], cloud systems in different locations [178], data storage and management [179], data streaming [180], and distributed storage systems [181]. The trend of big data architecture does not show a significant change.

Stock Market. This theme investigates the stock market

applications of Twitter data such as investigating the relationship between relevant Twitter trends and trends of stock options pricing [182], studying Twitter as a useful information resource for financial market activity [183], exploring the relationship between the Twitter daily happiness trend and the stock market trends [184], and examining the impact of positive, negative, and neutral tweets on price returns [185] and renewable energy stocks [186]. The stock market theme shows a positive extremely significant change indicating high research activities.

Recommendation System. This topic represents the Twitter-related studies focusing on recommendation systems for different purposes such as recommending new followers [187], detecting interests of users [188], and developing a personalized recommender system based on relationships of users [189], a personalized news recommender system utilizing news popularity on Twitter [190], and an emotion-based music recommender system [191]. The trend analysis does not show a significant change for the recommendation system topic.

Altmetrics. This topic considers non-traditional scholarly impact measurements based on web activities such as tweeting. This theme represents the studies analyzing research-related discussions on Twitter such as understanding the impact of online non-social media discussions on social media activities such as liking and tweeting [192], evaluating mentions of papers as an alternative method for research assessment [193] in different domains such as humanities [194] and dental research [195], and comparing alternative metrics such as Twitter mentions and traditional metrics like citations in medical education [196]. The altmetrics topic has a positive significant trend indicating high research activities. More discussions on altmetrics can be found in [197]–[202].

Survey. Using statistical techniques, this research method investigates a data sample collected from a population by traditional data collection techniques like developing a questionnaire. This topic represents the manuscripts in two directions. The first one is using surveys for studying Twitter-related issues such as investigating social media users' preference for oral health information searching [203], analyzing the relationship between gender, personality, and Twitter addiction [204], sleep disturbance and social media use [205], and eating concerns and social media use [206]. The second direction is posting a survey on Twitter to hire participants for research such as evaluating a home drinking assessment scale based on the initial psychometric properties [207]. The studies based on the survey topic have an extremely significant change with a positive trend. For more details on survey methods, refer to [208]–[211].

Experiment. This method investigates the impact of changing the independent variable (the cause) on the dependent variable (the effect). Experiment-related studies developed trials for different research purposes such as investigating the impact of social media activities on web visits of a journal [212], posting tweets on promoting knowledge products [213], developing engagement strategies on social

media webpage visits of a state health-system pharmacy organization [214], and lifestyle related tweets on weight loss [215], and examining the relationship between Twitter use, physical activity, and body composition [216]. The experiment theme has high research activity with an extremely significant change. More discussions and details on developing experiments can be found in [217], [218].

Natural Language Processing (NLP). This method utilized artificial intelligence techniques to analyze natural language text or speech. NLP has been utilized for different purposes on Twitter such as analyzing the use of diminutive interjections [219], the meanings of different combinations of hashtags starting with #jesuis [220], and the geographic patterns of African American Vernacular English posts [221], proposing a normalization method to convert Malay Tweet language to standard Malay [222], and decoding different languages on tweets [223]. Having an extremely significant change, the NLP theme has an increasing trend. For more discussion on NLP, refer to [224]–[228].

Public Relations. This theme is seen in papers which utilize Twitter in public relations for different firms such as non-profit organizations [229], media organizations [230], state health departments [231], global organizations [232], and Fortune 1000 companies [233]. The trend of public relations does not have a significant change over time.

Opinion Mining. While sentiment analysis explores public feeling about a given topic, opinion mining investigates the reasons or driving forces behind the public feeling. Within this topic, studies investigated public opinion with respect to different issues such as the 2015 Ireland same-sex marriage referendum [234], climate change [235], the Dakota access pipeline [236], the U.S. nuclear energy policy [237], and the 2011 Norwegian election [238]. Having an extremely significant change, the opinion mining theme has an increasing trend. For more discussions and details on opinion mining, refer to [86], [239].

Health Discussion. This theme shows Twitter-related studies focused on health topics such as orthodontic retention [240], lung cancer [241], depression and schizophrenia [242], diabetes [243], and mental health [244]. Having an extremely significant change, the health discussion theme has a positive slope.

Citizen-Government Interaction. This topic appears in studies which investigated the interaction between governments and citizens with respect to different issues such as foreign policy in Canada [245], public policy of the 75 largest U.S. cities [246], food policy in South Korea [247], the transparency of public agencies in Thailand [248], and presentational strategies of the Canadian Toronto Police Service [249]. The trend of the citizen-government interaction theme does not have a meaningful change.

Community Analysis. This topic represents the research which analyzed Twitter communities developed for different purposes such as peer-to-peer file sharing [250], developing personal communities [251], learning [252], and support for weight loss [253] and physical activity [254]. The community

analysis has a significant negative slope indicating decreasing research activities.

Marketing. This theme shows papers which analyzed Twitter data for marketing functions such as customer knowledge management [255], competitive advantage [256], consumer behavior analysis [257], consumer opinion analysis [258], and brand-building and customer acquisition [259]. Like community analysis, marketing has a significant decreasing trend.

Human Behavior. This topic shows studies which investigate the intersection of social networking and human behavior such as interpersonal relationships [260], bridging and bonding social capital [261], organizational processes and employee performance [262], face-to-face pro-social behaviors [263], and internal and external motivations for the use of social media [264]. The trend of human behavior does not have a meaningful change.

Social Network Analysis. This method utilizes graph theory to characterize the structure of social networks. This topic represents the studies which analyzed Twitter networks for different purposes such as consensus formation processes [265], classifying complex networks [266], and information diffusion methods like epidemic [267], null [268], and evolutionary game theory [269] models. The trend of social network analysis does not have a significant change. For extensive details and discussion on social network analysis, refer to [270]–[273].

Image/Video Analysis. This method uses qualitative approaches to code image/video data of online posts and categorize them. This topic is illustrated by studies that studied images and videos with respect to different issues such as fitness and thinness [274], the Boston marathon bombing [275], eating disorders [276], life experience [277], the online activists of Islamic State in Iraq and Syria (ISIS) [278]. The trend of image/video analysis does not have a meaningful change. For more discussion on image/video analysis, refer to [279], [280].

Drug. This topic shows Twitter-related studies investigated different drugs such as E-cigarettes [281], blunts [282], marijuana and alcohol [283], hookah [284] and opioids [285]. The Drug topic has a very significant positive slope indicating high research activities.

Activism. This topic illustrates the studies which investigated Twitter activism such as feminism [286], African American activism [287], resistance to political movements [288], indigenous activism [289], and anti-racism [290]. The activism topic has a very significant positive slope indicating high research activities.

Web Technology. This theme represents the papers focused on web technology issues such as comparing Application Programming Interfaces (APIs) of multiple companies like Twitter and Facebook [291], exploring different web development platforms [292], analyzing different aspects of open APIs [293], archiving social media (Web 2.0) content [294], and developing new open source applications based on the Twitter API to archive data for research purposes [295].

The web technology topic has a significant negative slope indicating decreasing research activities.

Graph Mining. This method explores the characteristics of graphs to recognize and predict patterns. This topic includes studies that utilized Twitter data for the evaluation of graph mining models developed for different purposes such as clustering [257], triangle counting [296], anomaly detection [297], understanding dynamic graphs [298], and graph-constrained coalition formation [299]. Having an extremely significant change with a positive slope, the graph mining theme has high research activities. For more discussion on graph mining, refer to [300]–[302].

Pedagogical Use. This theme illustrates the studies that used Twitter for educational purposes such as enhancing learning [303], engaging students [304], designing an open online course [305], professional purposes [306], and developing a professional learning network [307]. Having an extremely significant change, the pedagogical use theme has a negative slope.

Security. This topic shows studies which proposed detection methods for security issues such as spams [308], social bots [309], malicious accounts [310], fake identities [311], and suspicious URLs [312]. The security topic has a very significant change with an increasing trend.

IV. DISCUSSION

To better understand the growing field of Twitter-related studies, this study provides a bird's eye view to explore the overall and temporal patterns of major topics within the past years of Twitter related papers. This research has some methodological advantages over traditional literature review studies. First, traditional methods were limited to a small sample of related papers, while this study investigates all relevant papers in three well known and popular databases. Second, traditional methods develop a codebook based on studying a data sample to detect themes within a set of papers. It is humanly impossible to recognize all themes within scholarly publications, but this research utilizes an unsupervised machine learning technique that is an efficient approach that does not need the codebook. Third, previous research defined the total number of themes in traditional methods, while this paper applies an estimation method to find the optimal number of topics. Fourth, while previous studies selected a sample of papers for the traditional qualitative coding, we use a computational approach to find the most related papers for each of the topics systematically. Fifth, the topic discovery process in this paper has been implemented in an efficient process; in comparison, traditional methods face a time-consuming and labor-intensive process.

Among the meaningful and relevant topics, while 23.7% of topics did not show a significant trend over time, 55.3% had increasing (hot) and 21% had decreasing (cold) trends. These topics can be discussed in three categories: (1) application, (2) methodology, and (3) technology (Table 4). The topics in the first category are made up of studies which utilized Twitter data for different applications including business

and management such as marketing, education like medical pedagogy, health such as disease surveillance, media like social media platforms, politics such as elections, and psychology and society like information behavior. The second category indicates the methodology related topics in six sub-categories:

- computational (analytical) techniques (e.g., sentiment analysis)
- qualitative techniques (e.g., traditional content analysis)
- mixed methods using a computational techniques (e.g., text mining) for detecting topics in a corpus and a qualitative approach (e.g., coding) for disclosing the theme of topics
- quantitative techniques (e.g., survey)
- research facilitation to find and hire participants by posting surveys on Twitter
- data resources for evaluating new methods

The third category of topics investigated different technological aspects of social media such as APIs. While the technology related topics have a negative slope, all the methodology-related and most of the application-related topics had high research activities between 2009 and 2018.

Among the application-related topics, politics, stock market, and information behavior were the top hot topics, and marketing, ethics, law, and privacy, and medical education were the top cold topics. Considering the methodology related topics, while survey and experiment are traditional qualitative and quantitative methods, the rest of methodologies are computational methods. Therefore, it seems that the large scale of Twitter data was the reason that the research activities using the computational research methods were more prevalent than the ones applying the qualitative and quantitative methods. Table 4 shows sentiment analysis, big data mining, and topic modeling were not only the hot topics but also the high-ranking topics among all the detected topics. In the technology category, the meaningful trends were decreasing, indicating low research activities. Increasing or decreasing trends can also correspond to the research needs and opportunities [313].

In summary, evidenced by the increasing number of publications and trend of most topics having a significant change, Twitter-based research will continue to evolve in formal sciences (e.g., computer science), natural science (e.g., health), and social science (e.g., political science). Due to the positive slope in Figure 4, we also expect to see more Twitter-based research activities in the following years, overall.

Our findings show that researchers utilized different data sizes including a few thousand (small scale), several hundred thousand (medium scale), and millions (large scale) of data records on Twitter. These studies used structured data (e.g., the number of followers) or unstructured data (e.g., image/video and tweets), which unstructured data has been investigated more than structured data on Twitter.

Researchers applied qualitative, quantitative, computational (analytics), and mixed methods to address their research goals and questions. Due to the massive number of

TABLE4: Categories of topics. The topics with $P < 0.05$ ranked from the highest to the lowest slope values.

Category	Trend		
	$P < 0.05$		$P \Rightarrow 0.05$
	$Slope > 0$	$Slope < 0$	
Application	Politics Stock Market Activism Information Behavior Health Discussion Social Media Platforms Security Disease Surveillance Sport/Entertainment Drug	Marketing Ethics, Law, and Privacy Medical Education Pedagogical Use Community Analysis	Disaster Analysis Social Movement Public Relations Citizen-Government Interaction Human Behavior
Methodology	Sentiment Analysis Graph Mining Big Data Mining Topic Modeling Content Analysis Spatial Analysis Survey Opinion Mining Altmetrics Experiment NLP	NA	Social Network Analysis Image/Video Analysis
Technology	NA	Social Media Technology Web Technology Digital Communication	Big Data Architecture Recommendation System

tweets, the most popular research approaches were computational methods, including supervised methods such as classification techniques and unsupervised methods like clustering techniques.

The recognized static and dynamic patterns disclose a macro-level perspective into some aspects as follows. First, the frequency analysis provides an overall picture of the Twitter-related studies. Second, the detected topics illustrate major Twitter research themes. Third, the weight of topics shows the importance or popularity of topics. Fourth, the temporal topic analysis demonstrates the changes in research interests during the time frame. Fifth, the detected trends help to provide an overview of past studies and offer insight for future studies. Sixth, the top words of topics can be used as keywords to assist researchers in finding relevant studies with respect to a topic for more in-depth analysis of that topic.

This study is beneficial to researchers for understanding the larger picture of Twitter-related studies and their trends, to educators for defining the scope of social media related courses, to journal editorial boards and publishers for categorizing research topics in social media, to publishers for investing more on hot topics, and to science policymakers and funding agencies for developing strategic plans.

V. CONCLUSION

This research proposes a systematic framework to have a better understanding of Twitter-related studies and their hot and cold topics. Our findings show the potential of this research to understand large-scale research corpora and the usefulness of text mining and trend analysis to investigate research themes and their trends in an efficient time-frame. Some key conclusions of this research are as follows:

- The number of Twitter publications has been increased significantly since 2006 and is expected to grow in the following years.
- Sentiment analysis, social network analysis, big data mining, topic modeling, and content analysis were the most discussed topics.
- There were more research activities in application and methodology related topics than the ones in technology related topics.
- Most of the topics with meaningful trend ($P < 0.05$) had an increasing trend ($Slope > 0$).
- While different research approaches were used, supervised and unsupervised computational methods were discussed more than traditional research methods.
- Different data types (structured and unstructured) and data scales (small, medium, and large size) have been studied in the literature.
- Twitter was used as not only a data source but also a facilitator for hiring research participants.
- Twitter has been studied by researchers in formal, natural, and social sciences.
- Twitter-based research is a growing field recognized for population-level data.
- The collaboration of formal, natural, and social sciences on investigating Twitter data shows that Twitter-based research is an interdisciplinary field.
- Compared to traditional literature review methods, the methods of this paper are systematic, fast, and efficient.

While this survey paints a picture to illustrate where Twitter-related studies have been during the past years and might go in the following years, it has some restrictions. First, our data collection was limited to three databases. Second,

this study did not consider other social media platforms (e.g., Facebook) to compare the research of multiple platforms. Third, this research focused on manuscripts published in English. Fourth, while this research is a high-level analysis providing a good overview of major topics and trends, it does not capture a full meaning of our data and sub-categories of the detected topics. Considering these limitations, future directions may consider other databases such as Scopus (<https://www.scopus.com>), multiple social media platforms, non-English-language publications, and investigating each of the detected topics to find sub-topics.

AMIR KARAMI is an Assistant Professor in the College of Information and Communications, a Faculty Associate at the Arnold School of Public Health, and Social Media Core Director at the Big Data Health Science Center (BDHSC) at the University of South Carolina. His research interests are social media analysis, text mining, computational social science, and medical/health informatics. His research was published in different journals such as the *Information Processing & Management*, *Journal of Biomedical Informatics*, *International Journal of Fuzzy Systems*, and *International Journal of Information Management*, and conferences like the *Association for Information Science and Technology (ASIS&T) Annual Meeting*, *iConference*, *Hawaii International Conference on System Science (HICSS)*, and *International Conference on Data Mining (ICDM)*.

MORGAN LUNDY is a dual Masters' student in the College Of Arts and Sciences and the College of Information and Communication at the University of South Carolina. Her research interests include social media analysis, health informatics, and data science.

FRANK WEBB is a student in the South Carolina Honors College at the University of South Carolina. His research interests are social media analysis, health informatics, and data science. His work has been published in the Southern Association for Information Systems (SAIS) and the Annual Meeting of Association for Information Science and Technology (ASIS&T).

YOGESH K. DWIVEDI is a Professor of Digital Marketing and Innovation, Founding Director of the Emerging Markets Research Centre (EMaRC) and Co-Director of Research at the School of Management, Swansea University, Wales, UK. Professor Dwivedi is also currently leading the International Journal of Information Management as its Editor-in-Chief. His research interests are at the interface of Information Systems (IS) and Marketing, focusing on issues related to consumer adoption and diffusion of emerging digital innovations, digital government, and digital marketing particularly in the context of emerging markets. Professor Dwivedi has published more than 300 articles in a range of leading academic journals and conferences that are widely cited (more than 14 thousand times as per Google Scholar). Professor Dwivedi is an Associate Editor of the European Journal of Marketing, Government Information Quarterly and International Journal of Electronic Government Research, and Senior Editor of the Journal of Electronic Commerce Research.
